CREATING GROUPS.

1. Create a local group with all the local users. In Windows 7/10 (Client)

Un grupo local no es lo mismo que un grupo de Ámbito local (que ya sí que sería de dominio)

2.. Look for some information about the kind of groups you can create in Windows Server and their scope:

Three types of groups:

Domain local groups is the most intuitive idea of a group. It's members come from any domain in the forest and it's used to access a domain resourses.

While a Domain Local Group can give permissions only for resources in its own domain, it may have members from anywhere in the tree or forest.

A global group can contain any domain local groups from the same domain and any global and universal from any domain in the forest. Can be given permissions to any resource in a domain and it's not stored in the global cataloge.

Any user from any domain, or any global or universal group from any domain can be a member of a universal group, so it's better to use universal groups sparingly. It's used to access ressourses in any domain.

Recommendations:

- Domain local groups should be used to assign permissions to an object within a domain.
- Global groups should be used to give permissions to resources.

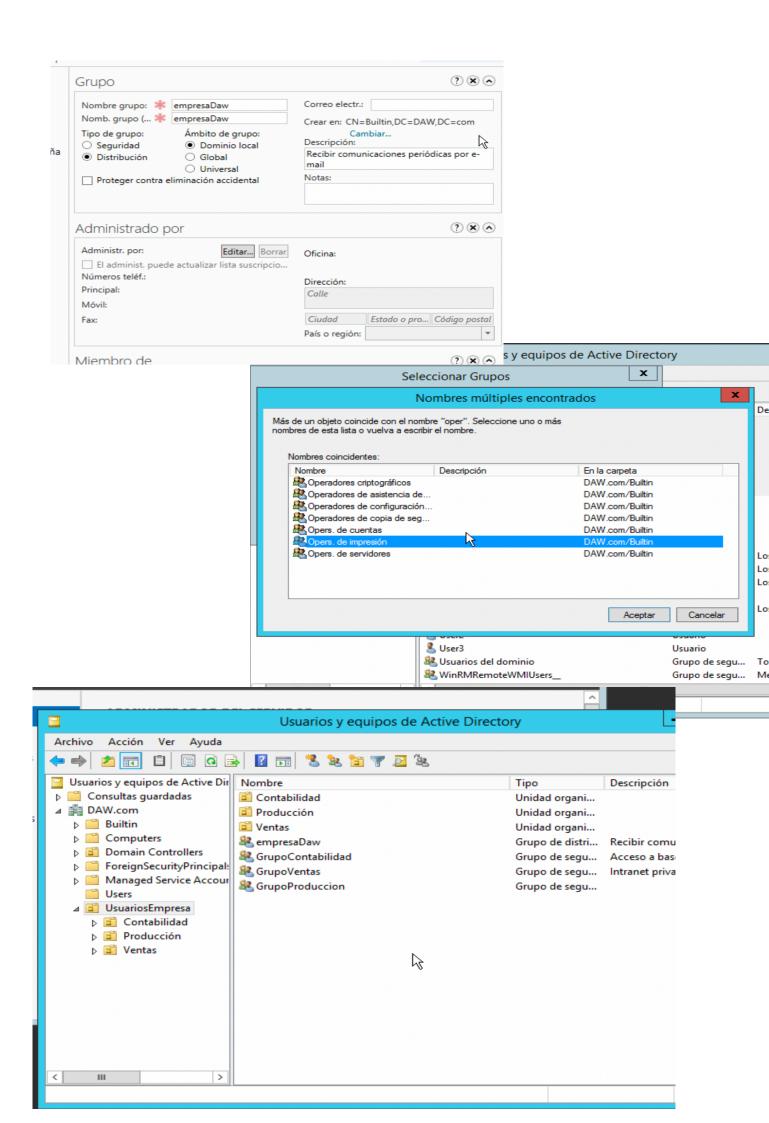

Use Universal groups to gather groups together

• If individual users are placed into universal groups, these users will be listed in the global catalogue.

3. Create the whole structure of groups in the domain DAW based on the following table:

Empleado	Necesita acceder a
Todos	Recibir comunicaciones periódicas por e- mail
Dpto. Ventas	Informes de ventas
Dpto. Producción	Base de datos de inventario
Dpto. Ventas	Base de datos de clientes
Dpto. Contabilidad	Base de datos de clientes
Todos	Impresoras de la empresa
Con contrato indefinido	Intranet privada de la empresa
Grupo de prácticas	Administración de copias de seguridad

El la primera unidad organizativa es distributiva y el resto son de seguridad Para Impresoras de la emrpesa he seleccionado uno a uno desde usuarios de active directory y les he añadido al grupo builtin. Screenshots:

4. If the company headquarters is located in Paris and there are administrators who need access to the Inventory database to perform their work. What would you do to ensure that the administrators that require access to the database of the inventory?

Since they are located in differtent domain in a forest I would include the headquarters in a global group that I create where the resource is, in this case I assume that DAW is already in a forest.

5. Now imagine that the company has a three-domain environment, the domain root in Paris and the other two domains in Australia and Italy. Administrators of the three domains need access to the database of inventory in Paris to do their jobs. What would you do to ensure that administrators have the access they require?

I would create the global group in the domain root so that I can include user from other domains.

6. Which is the easiest way to give to a user full control over all the computers in a domain?

I would include the computers in the administrators group.
